1 Introduction

FunciSNP assist in identifying putative functional SNP in LD to previously annotated GWAS SNPs (tagSNP). Extracting information from the 1000 genomes database (1kg) by relative genomic position of GWAS tagSNP currated for a particular trait or disease, FunciSNP aims to integrate the two information with sequence information provided by peaks identified from high-throughput sequencing. FunciSNP assumes user will provide peaks identified using any available ChIP peak algorithm, such as FindPeaks, HOMER, or SICER. FunciSNP will currate all 1kg SNPs which are in linkage disequilibrium (LD) to a known disease associated tagSNP and more importantly determine if the 1kg SNP in LD to the tagSNP overlaps a genomic biological feature.

Correlated SNPs are directly imported from the current public release of the 1000 genomes database. 1000 genomes ftp servers available for the 1000 genomes public data:

- National Center for Biotechnology Information (NCBI)¹
- \bullet European Bioinformatics Institute (EBI)²

¹ftp://ftp-trace.ncbi.nih.gov/1000genomes/

²ftp://ftp.1000genomes.ebi.ac.uk/vol1/

Correlated SNPs in LD to a tagSNP and overlapping genomic biological features are known as putative functional SNPs.

This vignette provides a 'HOW-TO' guide in setting up and running FunciSNP on your machine. FunciSNP was developed with the idea that a user will have uninterupted high-speed internet access as well as a desktop machine with more than 4 multiple cores. If user is using a windows machine, multiple cores options will not work and thus total time to complete initial FunciSNP analysis will take longer than expected. Be sure you have uninterupted computing power when using a windows machine. If using a linux machine, please use 'screen' (see 'man screen' for more information).

1.1 Benchmark

Using a 64bit Linux machine running 11.04 Ubuntu OS with 24G RAM and 8 cores connected to a academic high-speed internet port, the amount of time to complete 99 tagSNP across 20 different biofeatures took less than 30 min to complete. We anticipate about 2 hours to complete the same analysis using one core.

1.2 Genome-Wide Association Studies SNP (GWAS SNP)

Genome-wide association studies (GWASs) have yielded numerous single nucleotide polymorphisms (SNPs) associated with many phenotypes. In some cases tens of SNPs, called tagSNPs, mark many loci of single complex diseases such as prostate (> 50 loci), breast (> 20 loci), ovarian (>10 loci), colorectal (>20 loci) and brain cancer (>5 loci) for which functionality remains unknown. Since most of the tagSNPs (>80%) are found in non-protein coding regions, finding direct information on the functional and/or causal variant has been an important limitation of GWAS data interpretation.

1.3 1000 genomes project (1kg)

The 1000 genomes project recently released a catalog of most human genomic variants (minor allele frequency of >0.1%) across many different ethnic populations. Initially, the 1000 genomes project goal was to sequence up to 1000 individuals, but has since sequenced more than 2000 individuals, thereby increasing our current knowledge of known genomic variations which currently sits at just over 50 million SNPs genome wide (approx. 2% of the entire genome and on average 1 SNP every 60 base pairs)

1.4 Genomic features (Biofeatures)

With the advent of advanced sequencing technologies (next-generation sequencing, NGS), genomic regulatory areas in non-coding regions have been well characterized and annotated. Coupled with chromatin immuno-precipitation for a protein (e.g. transcription factor of histone) of interest, also known as ChIPseq, the technology have provided us with a unique view of the genomic landscape, thereby providing a wealth of new knowledge for genomics

research. Work by large consortia groups such as the Encyclopedia of DNA Elements (ENCODE), the Roadmap Epigenomics Mapping Consortium and The Cancer Genome Atlas (TCGA), have made publicly available a growing catalog of many different histone marks, transcription factors and genome-wide sequencing datasets for a variety of different diseases and cell lines, including well characterized cancer cell lines such as MCF7 (breast cancer), HCT116 (colon cancer), U87 (brain cancer) and LNCaP (prostate cancer).

2 Installing and Loading FunciSNP

Currently, there are two options to obtain a copy of FunciSNP:

- Download current source code from Coetzee's lab³
- Download and install from Bioconductor⁴

If you download the source code from either method above, you can install *FunciSNP* by following the instructions described in R CRAN. By installing *FunciSNP* from source, the package assumes you have all the required libraries installed.

- Rsamtools (>= 1.6.1)
- rtracklayer(>= 1.14.1)
- GGtools (>= 4.0.0)
- methods
- ChIPpeakAnno (>= 2.2.0)
- GenomicRanges
- TxDb.Hsapiens.UCSC.hg19.knownGene
- VariantAnnotation
- plyr
- org.Hs.eg.db
- snpStats

The following loads the *FunciSNP* library in R.

```
> options(width=80);
> library(FunciSNP);
> package.version("FunciSNP");
[1] "0.2.0"
```

³http://coetzeeseq.usc.edu/publication/Coetzee_SG_et_al_2012/

⁴http://www.bioconductor.org

3 Running getFSNPs to identify putative functional SNPs

Before running getFSNPs, two input files are required. A list of tagSNPs and a folder with all available biological features (peak files in BED format).

3.1 Create a GWAS SNP file

GWAS SNPs (tagSNP) should be listed in a tab or whitespace separated file. Three columns are required for each tagSNP:

- Position (chrom:position)
- rsID (rsXXXXXXXXX)
- population (EUR, AFR, AMR, ASN, or ALL)

'Positon' should be the exact postion for each rsID as reported by human genome build hg19 (chrom:postion). 'rsID' should contain a unique rsID as determined by the 1000 genomes database (1kg)⁵ for each identified 'tagSNP'. Population should be a three letter code to determine original ethnic population for which the associated 'tagSNP' was identified. The three letter code should be either European (EUR), Asian (ASN), African (AFR), American (AMR), or All (ALL). List each tagSNP per ethnic population. If similar rsID was identified in multiple ethnic population, list each duplicate tagSNP separately with the appropriate ethnic pouplation.

Several GWAS SNPs significantly associated with Glioblastoma multiforme (GBM)⁶ were collected for this example. GBM is a brain cancer with median survival at less than 12 months, making this form of cancer one of the most aggressive of all cancer types. Currently, there is no known function of any of these associated tagSNPs. In this example, GBM includes lower grade glioma, therefore we use the 'glioma' to label all objects.

```
> ## Full path to the example GWAS SNP regions file for Glioblastoma
> # (collected from SNPedia on Jan 2012)
> glioma.snp <- file.path(system.file('extdata', package='FunciSNP'),
+ dir(system.file('extdata',package='FunciSNP'), pattern='.snp$'));
> gsnp <- read.delim(file=glioma.snp,sep=" ",header=FALSE);</pre>
> gsnp;
            V1
                      ٧2
                         V3
1 11:118477367
                rs498872 EUR
2
     5:1286516 rs2736100 ASN
3
    9:22068652 rs4977756 EUR
 20:62309839 rs6010620 EUR
```

⁵Be sure the rsID is located in this browser: http://browser.1000genomes.org/

⁶See http://www.snpedia.com/index.php/Glioma

3.2 Biofeatures in BED format

Each biofeature used to identify correlated SNP should be in standard BED format⁷. Each biofeature should be stored in one folder and should have file extension '*.bed'.

Here is an example of three different biofeatures used for this glioma example. NRSF and PolII (both transcription factors) where extracted from a recent release of ENCODE, as well as promoters of approximately 38,000 gene transcription start sites (TSS). Promoters are identified as +1000 to -100 base pair of each annotated TSS. In addition, we include all known DNAseI sites as supplied by ENCODE as well as FAIRE data. In addition, we used known CTCF sites to differentiate the DNAseI. The DNAseI and FAIRE data were extracted in April of 2012 and they represent the best known regions across several different cell lines. In addition, for the FAIRE data, we selected peaks with p-values less than 0.01.

```
> ## Full path to the example biological features BED files
> # derived from the ENCODE project for Glioblastoma U-87 cell lines.
> glioma.bio <- system.file('extdata',package='FunciSNP');</pre>
> #user supplied biofeatures
> as.matrix(list.files(glioma.bio, pattern='.bed$'));

                               Merged-chr7-129164-1
```

As an example, Nrsf was created to illustrate the format needed for each biofeatures. To run getFSNPs, only the path to the folder to each biofeature is required (glioma.bio).

3.3 getFSNPs analysis using two inputs

To run the example data could take more than 5 minutes, thus the R code is commented out for this tutorial. If you are interested in running the glioma example from scratch, please uncomment the following and rerun in your R session. NOTE: The main method to run FunciSNP is *getFSNPs*.

```
> ## FunciSNP analysis, extracts correlated SNPs from the
> ## 1000 genomes db ("ncbi" or "ebi") and finds overlaps between
> ## correlated SNP and biological features and then
> ## calculates LD (Rsquare, Dprime, distance, p-value).
> ## Depending on number of CPUs and internet connection, this step may take
> ## some time. Please consider using a unix machine to access multiple cores.
>
> # glioma <- getFSNPs(snp.regions.file=glioma.snp, bio.features.loc = glioma.bio,
> # bio.features.TSS=FALSE);
```

As an alternative, glioma was pre-run and stored in the package as an R object. To call this data object, simily run the following commands.

```
> data(glioma);
> class(glioma);

[1] "TSList"
attr(,"package")
[1] "FunciSNP"
```

Now, glioma contains the R data structure that holds all the results for this particular analysis. Each tagSNP is stored as a slot which contains associated correlated SNP and overlapping biofeature. It also contains a number of different annotations (see below for more details). To see a brief summary of the results (summary), type the following commands:

> glioma;

TagSNP List with 4 Tag SNPs and

1809 nearby, potentially correlated SNPs, that overlap at least one biofeature \$`R squared: 0.1`

	Total	R.sq >= 0.1	Percent
tagSNPs	4	4	100.00
1K SNPs	1809	136	7.52
Biofeatures	6	6	100.00

\$`R squared: 0.5`

	Total	R.sq>=0.5	Percent
tagSNPs	4	3	75.00
1K SNPs	1809	66	3.65
Biofeatures	6	4	66.67

\$`R squared: 0.9`

	Total	R.sq >= 0.9	Percent
tagSNPs	4	1	25.00
1K SNPs	1809	14	0.77
Biofeatures	6	3	50.00

As you can quickly observe from the above analysis, using 4 tagSNPs position and 7 different biological features (ChIPseq for 'NRSF', 'PolII', promoters of approx. 38,000 genes, DNAseI sites, DNAseI sites with CTCFs, FAIRE, CTCFs) as two types of input, FunciSNP identified 1809 1kg SNPs that overlap at least one biofeature. Each 1kg SNP contains an Rsquare value to the associated tagSNP. As a result, the first output (glioma), summarizes the analysis subsetted in three different Rsquare values (0.1, 0.5 and 0.9). If we consider Rsquare cutoff at 0.9 (Rsquare \geq 0.9), 14 1kg SNPs overlapping at least one biofeature. This value represents 0.77% of the total (1809). In addition, at this Rsquare cutoff, 3 biological features are represented among the 14 1kg SNPs.

> summary(glioma);

```

Running summary however will output a slightly different report yet just as informative. At three different Rsquare cutoffs (0.1, 0.5, 0.9), the summary output illustrates the tagSNP with the total number of 1kg SNPs overlapping a total number of biofeatures. For example, at Rsquare ≥ 0.5 , tagSNP 'rs6010620' is assocated with 53 different 1kg SNPs which overlap at least one biofeature, and 11 of them overlap at least two biofeatures.

Each newly identified 1kg SNP is now defined as putative functional SNP since they are in LD to an associated tagSNP and they overlap at least one interesting biological feature. Thus, each 1kg SNP can now be defined as 'YAFSNP' or 'putative functional SNP.'

4 Annotating newly identified putative functional SNPs

All known genomic features (exon, intron, 5'UTR, 3'UTR, promoter, lincRNA or in gene desert (intergentic)) are used to annotate each newly identified YAFSNP as described above. Information stored in this glioma.anno is used for all summary plots, table, and to output results in BED format (see following sections for more details). The following step will output the data.frame.

```
> glioma.anno <- FunciSNPAnnotateSummary(glioma);
> class(glioma.anno);

[1] "data.frame"
> gl.anno <- glioma.anno;
> ## remove rownames for this example section.
```

```
> rownames(gl.anno) <- c(1:length(rownames(gl.anno)))</pre>
> dim(gl.anno);

As you can see, each tagSNP ('tag.snp.id') is associated with an identifiable YAFSNP ('corr.snp.id') and each are associated with a biological feature ('bio.feature'). Additional columns are included which assist in summarizing the final results.

Now, if you prefer, you can use several functions to help summarize and plot the final analysis or you can use your own set of scripts to further summarize the results. Either case, the final results are stored in glioma.anno.

5 Summarize FunciSNP results

The following sections describe methods to summarize and plot the newly identified YAFS-NPs.

5.1 Summary table used to describe newly identified YAFSNPs

Using a specified Rsquare value (0-1) to subset the data, a table is generated which summarizes the total number of YAFSNPs, associated tagSNPs, and number of overlapping biofeatures. This will provide user a first look at the total number of available YAFSNP at a particular Rsquare cutoff.

The output is very similar to the output generated by calling glioma. But instead of getting a summary report three distinct Rsquare cutoffs, you can now specify the Rsquare cutoffs. In this case, we used rsq = 0.44 (to get a more objective rsq value, see figure 1 on page 17.

> FunciSNPtable(glioma.anno, rsq=0.44);

	Total	R.sq>=0.44	Percent
tagSNPs	4	4	100.00
1K SNPs	1809	73	4.04
Biofeatures	6	5	83.33

If 'geneSum' argument is set to 'TRUE', a list of gene names is reported instead which informs on the nearest gene symbols to the set of YAFSNPs. Only unique gene symbols are reported since multiple distinct YAFSNP can be near the same gene.

> FunciSNPtable(glioma.anno, rsq=0.44, geneSum=TRUE);

	Gene_Names
1	ARFRP1
2	CDKN2B
3	LIME1
4	PHLDB1
5	RTEL1
6	SLC2A4RG

```
7 STMN3
8 TERT
9 TNFRSF6B
10 TREH
```

5.2 Summary of correlated SNPs overlapping biofeatures

FunciSNPsummaryOverlaps function helps to determine the total number of YAFSNPs overlapping a number of different biofeatures. This is similar to running summary on glioma above, except now you can specifically call the function and set a pre-determined 'rsq' value to subset the data and thereby obtain a more objective and informative result.

> FunciSNPsummaryOverlaps(glioma.anno)

	bio.1	bio.2	bio.3	bio.4
rs2736100	144	9	0	0
rs4977756	114	43	1	0
rs498872	121	35	5	1
rs6010620	403	113	35	10
TOTAL # 1kgSNPs	782	200	41	11

Using a 'rsq' value, the output is subsetted to summarize the results with Rsquare values ≥ 'rsq'.

> FunciSNPsummaryOverlaps(glioma.anno, rsq=0.44)

	bio.1	bio.2	bio.3	bio.4
rs2736100	1	0	0	0
rs4977756	9	3	0	0
rs498872	7	3	0	0
rs6010620	56	13	7	3
TOTAL # 1kgSNPs	73	19	7	3

5.3 Summary of correlated SNPs for a number of different tagSNPs

After running FunciSNPsummaryOverlaps, the next question one would like to know is which correlated SNPs overlapping a number of different biofeatures for a number of associated tagSNP. Thus, in the example above, we have determined that we are interested in learning more about the YAFSNPs associated with 'rs6010620' and which overlap at least 3 different biofeatures.

```
> rs6010620 <- FunciSNPidsFromSummary(glioma.anno, tagsnpid="rs6010620",
+ num.features=2, rsq=0.44);
> #summary(rs6010620);
> dim(rs6010620);
```

```
[1] 36 28
> class(rs6010620);
[1] "data.frame"
> ## See FunciSNPbed to visualize this data in a genome browser.
```

6 Plot FunciSNP results

6.1 Default plot

FunciSNPplot is a function developed to plot various types of plots to summarize and assist end-user in making informed discoveries of FunciSNP results. Plots can be stored in a folder for future reference. Most plots were created in with the idea that they can be directly outputted in presentations or publication formats.

The following example plots the distribution of the Rsquare values for each YAFSNP (Figure 1, page 17). We recommend attempting this plot before subsetting any data by a specified rsq value. The distribution helps to identify a specific Rsquare value that will provide the most informative discovery.

```
> pdf("glioma_dist.pdf")
> FunciSNPplot(glioma.anno)
> dev.off()
null device
1
```

Figure 1 (page 17) illustrates the total number of YAFSNPsbinned at different Rsquare cutoffs. As you can see in this figure (1, page 17), there are a total of 13 YAFSNP with an Rsquare ≥ 0.9 . Since this plot does not take into consideration unique YAFSNP the number may represent duplicate YAFSNP since they may overlap more than one biological feature.

6.2 Split by tagSNP

Using 'splitbysnp' argument, the same type of plot as above (Figure 1, page 17) is generated, however the total number of YAFSNPs are now divided by the associated tagSNP (Figure 2, page 18). It should be clear from this plot that 3 of the 4 tagSNP have a number of YAFSNP with Rsquares ≥ 0.5 . And one tagSNP contains many more YAFSNP ('rs6010620').

```
> FunciSNPplot(glioma.anno, splitbysnp=TRUE)
> ggsave("glioma_dist_bysnp.pdf")
```

Distribution of 1kgSNPs by R² values Total # of 1kgSNPs: 2400

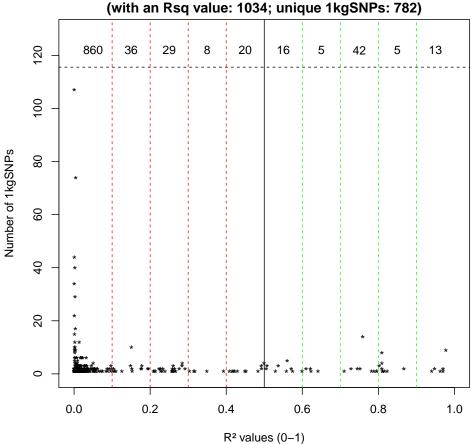

Figure 1: Distribution of Rsquare values of all YAFSNPs. Each marked bin contains the total number of YAFSNPs (correlated SNPs). The sum of all the counts would total the number of correlated SNPs.

6.3 Heatmap of 1kg SNPs by tagSNP vs Biofeature

Now, if you are interested in knowing which biofeature and associated tagSNP contains the most number of 1kg SNPs, run the following.

```
> pdf("glioma_heatmap.pdf")
> FunciSNPplot(glioma.anno, heatmap=TRUE, rsq = 0.1)
> dev.off()
```

X11cairo

2

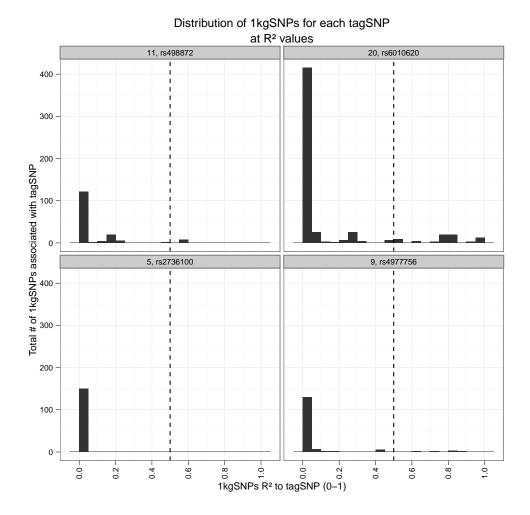

Figure 2: Distribution of Rsquare values of all YAFSNPs divided by the tagSNP and by its genomic location.

6.4 TagSNP and Biofeature Summary

Using 'tagSummary' argument will automatically save all plots in a specific folder. This is done because this function will generate a summary plot for each biofeature. The first plot (Figure 4, page 20) is a scatter plot showing the relationship between Rsquare and Distance to tagSNP for each YAFSNP.

- > ## Following will output a series of plots for each biofeature at rsq=0.5 > FunciSNPplot(glioma.anno, tagSummary=TRUE, rsq=0.5)
- Finished plotting 1 / 6
- Finished plotting 2 / 6
- Finished plotting 3 / 6

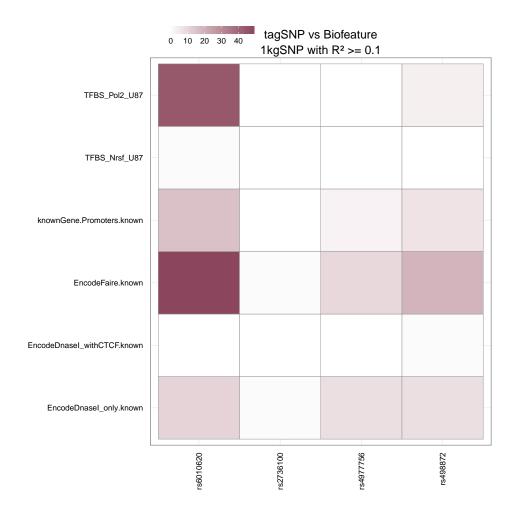

Figure 3: Heatmap of the number of 1kg SNPs by relationship between tagSNP and biofeature.

```
Finished plotting 4 / 6
Finished plotting 5 / 6
Finished plotting 6 / 6
```

Figure 4 on page 20 helps identify the relative postion of all newly identified YAFSNP to the associated tagSNP. As highlighted in figure 4, it is clear that tagSNP 'rs6010620' contains many more YAFSNP with Rsquares ≥ 0.5 , and the majority of them are within 40,000 base pairs of the tagSNP. There are a few YAFSNP which are more than 50,000 base pairs away while some are within 5,000 base pairs.

The second plot (Figure 5, page 21) is a histogram distribution of total number of YAF-SNPs at each Rsquare value. This plot is similar to Figure 2 on page 18, except it is further divided by biofeature. Each set of plot is further divided by tagSNP to help identify locus

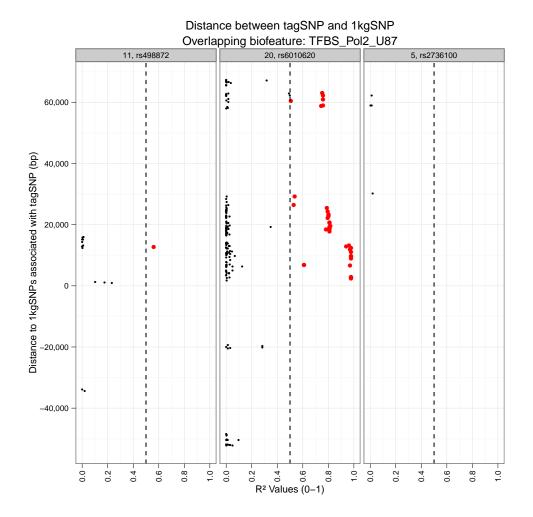

Figure 4: Scatter plot showing the relationship between Rsquare and Distance to tagSNP for each getFSNPs

with the most identifiable YAFSNP. This argument is best used in conjunction with a 'rsq' value.

6.5 Genomic Feature Summary

Using 'genomicSum' argument set to 'TRUE' will output the overall genomic distribution of the newly identified YAFSNPs (Figure 6, page 22). Using 'rsq' value, the plot is divided into all YAFSNPs vs subset. This type of plot informs the relative enrichment for genomic features.

- > pdf("glioma_genomic_sum_rcut.pdf")
- > FunciSNPplot(glioma.anno, rsq=0.5, genomicSum=TRUE, save=FALSE)

Distribution of 1kgSNPs R² divided by tagSNP & Overlapping biofeature:

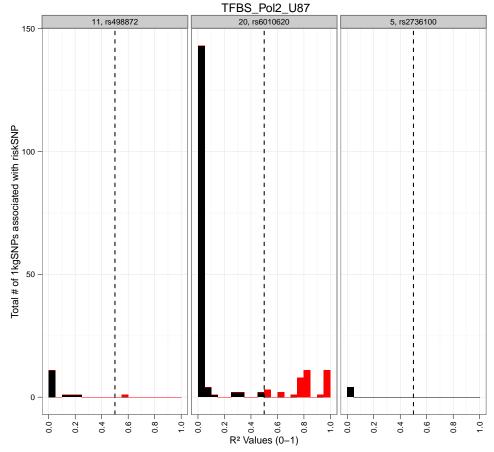

Figure 5: Histogram distribution of number of correlated SNPs at each Rsquare value

> dev.off()

X11cairo

2

Figure 6 on page 22 illustrates the distribution of the YAFSNP by genomic features. It is clear by using an Rsquare cutoff of 0.5, there is a slight enrichment of YAFSNP in introns and exonds and a depletion at promoters and other coding regions as well as intergentic regions.

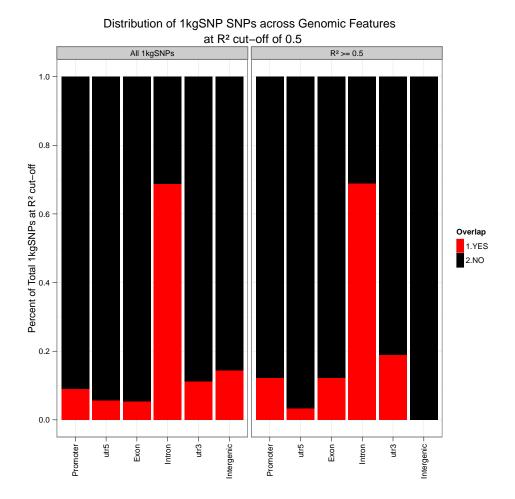

Figure 6: Stacked bar chart summarizing all correlated SNPs for each of the identified genomic features: exon, intron, 5UTR, 3UTR, promoter, lincRNA or in gene desert. Rsquare cutoff at 0.5. This plot is most informative if used with a rsq value.

7 Visualize FunciSNP results in a genomic browser (outputs BED format)

Finally, after evaluating all results using the above tables and plots functions, a unique pattern emerges that helps identify a unique cluster of tagSNP and biofeature that can identify a set of YAFSNPs. To better visualize and to get a better perspective of the location of each newly identified YAFSNP, the results can be outputted using *FunciSNPbed*.

FunciSNPbed outputs a unique BED file which can be used to view in any genomic browser which supports BED formats. To learn more about BED formats, see UCSC Genome Browser FAQ (http://genome.ucsc.edu/FAQ/FAQformat).

- > ## will output to current working directory.
- > FunciSNPbed(glioma.anno, rsq=0.22);

Total corSNP (RED): 107
Total tagSNP (BLK): 4

> # FunciSNPbed(rs6010620, rsq=0.5);

Each tagSNP which is in LD to a corresponding YAFSNP overlapping at least one biofeature is colored black, while the YAFSNP is colored red. The initial position is provided by the first tagSNP and the first linked YAFSNP. We recommend using UCSC genome browser to view your BED files. This is useful so you can view all public and private tracks in relation to FunciSNP results. As an example, see Figure 7 on page 23 or visit this saved UCSC Genome Browser session: http://goo.gl/xrZPD.

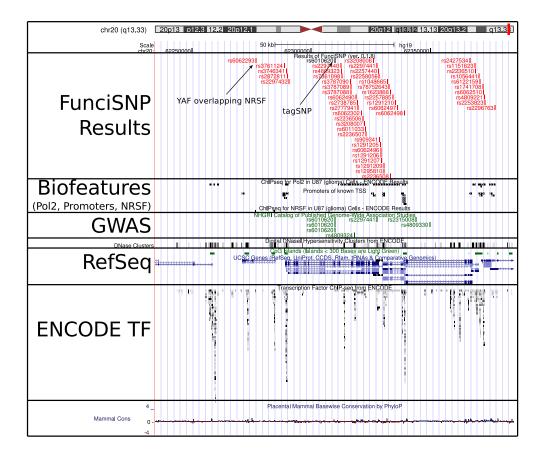

Figure 7: FunciSNP results viewed in UCSC genome browser. Top track represents FunciSNP results, second track is the known GWAS hits.
